ABZENA

Abstract

Relative potency assays are a critical part of a drug's lifecycle. They are designed to ensure that the efficacy and potency of manufactured batches, drug substance and drug product is maintained throughout drug development and once the drug is in the market. This is particularly important for biologics with complex MoAs. For example, a successful antibody drug conjugate (ADC) requires multiple steps including binding to its target, internalization, release of payload intracellularly, and elimination of tumour cells via the payload's mode of action. An ideal relative potency assay captures all of these processes, and reports on the final biological outcome.

Moving Medicine Forward

Your bioconjugate and complex biologics focused CDMO + CRO with:

- → Fully integrated early R&D through commercial capabilities
- High-quality & trusted data that drives development
- Streamlined regulatory support tailored to your program

At Abzena, we offer a phase-based approach for relative potency assay development based on the needs of our customers and where they are in their drug development lifecycle and provide GMP-ready testing once the assay is validated. Here we present Abzena's approach on developing relative potency assays for an ADC biosimilar. At the initial stages of the project, an antigenbinding ELISA was developed to support the testing of early batches and formulation samples for pre-clinical testing. To progress the project for clinical testing, a cell-based cytotoxicity assay was developed to support lot release testing as well as stability and toxicology studies. We present our approach for early feasibility studies, assay development, as well as validation. This streamlined process minimizes the risks, timelines and costs to develop and validate phase-appropriate relative potency bioassays for ADC biosimilars.

Antibody Drug Conjugates

ADCs combine the key design elements of small & large molecules:

Linker Payload Only a small proportion of The linker ensures the pavload remains attached administered ADCs actually to the mAb in general reach the tumour tissue, so circulation whilst allowing highly potent payloads are required to achieve release of the payload mAb specificity allows therapeutic efficacy inside the tumour cell delivery of the payload selectively to cells expressing the target antigen

Receptor binding Receptor binding Receptor-mediated endocytosis Free Drug Lysosomal degradation Drug release Drug release

ADCs have a multi-step mechanism of action with specific

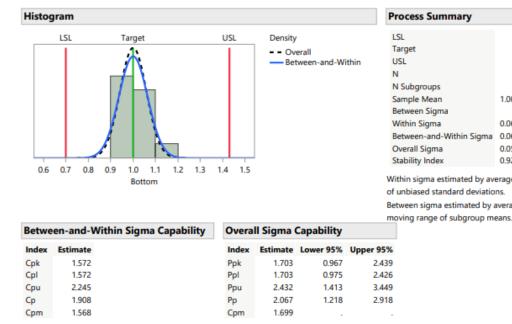

requirements for each step / component.

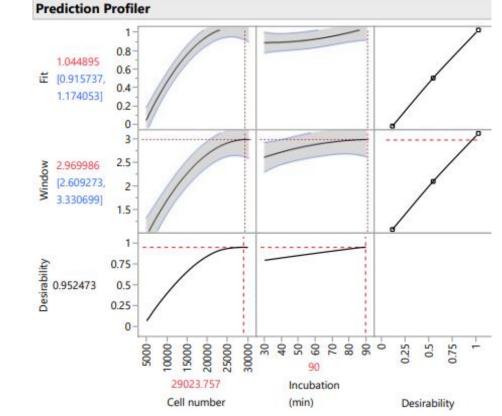

Thorough Development Strategy for Assay Design

Data Driven De-Risking During Assay Development

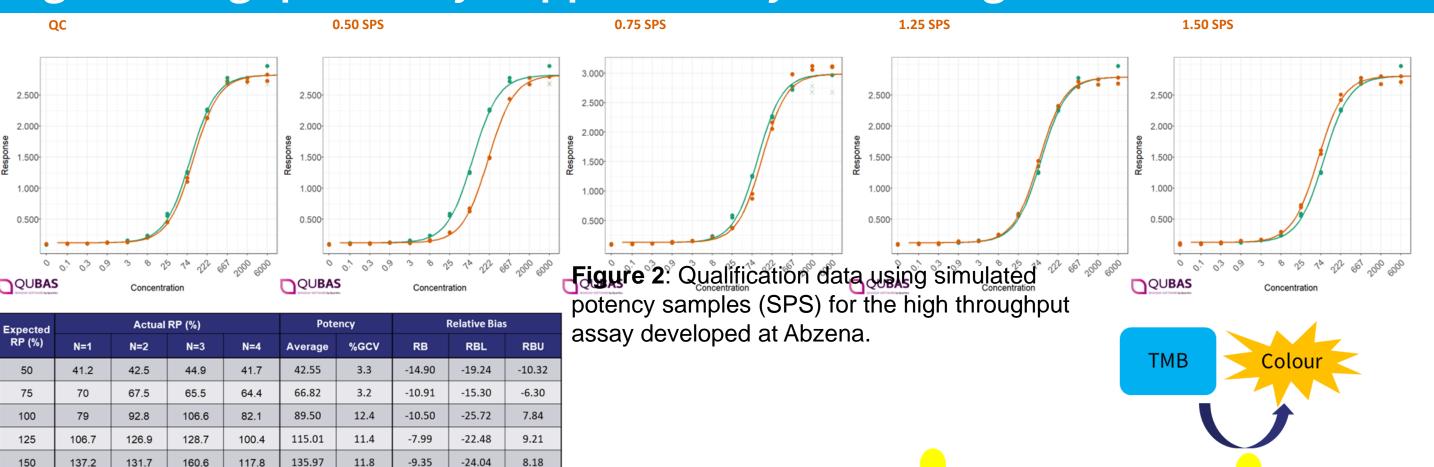

Abzena uses Design of Experiments (DoE) to efficiently optimise assays.

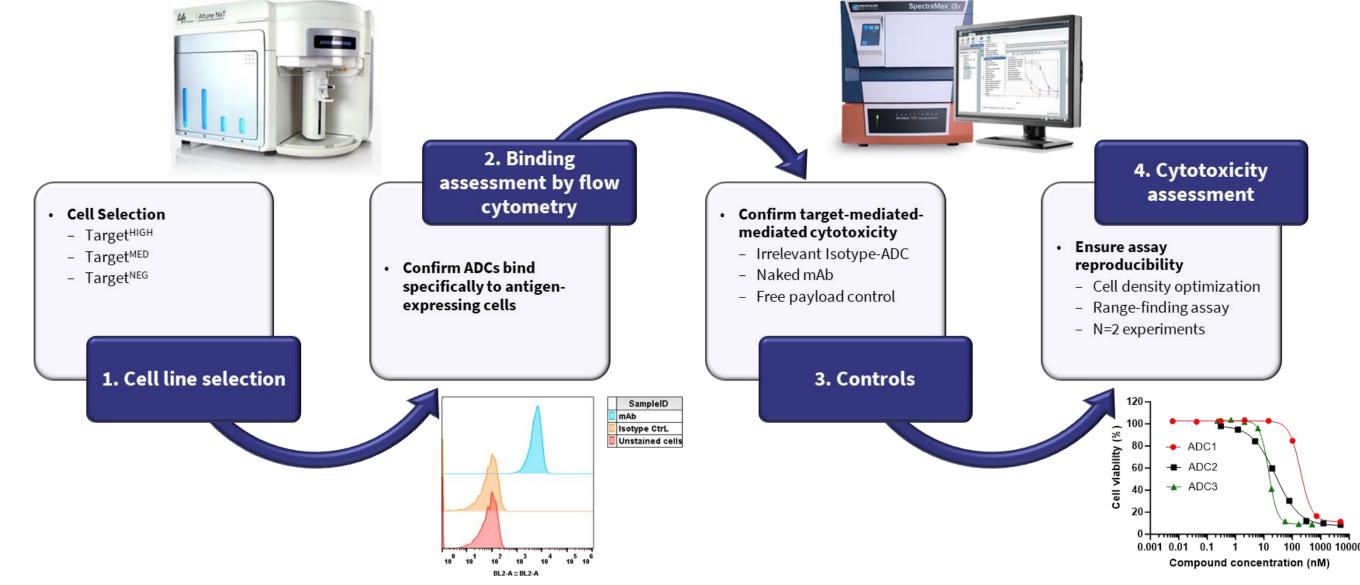

Abzena trends all data generated throughout development and testing to de-risk assays.

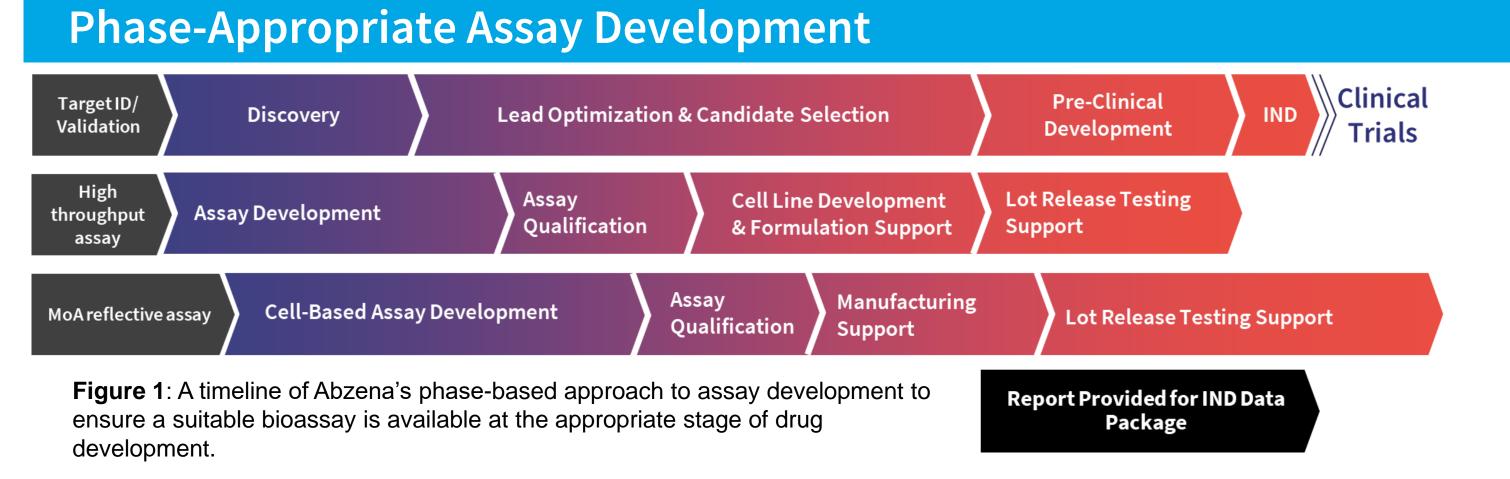

High Throughput Assay Supports Early Screening Studies

Abzena has a comprehensive development process captured in detailed reports for IND submissions.

The data package Abzena provides validates the use of target cell lines for MoA reflective cytotoxicity

Coating plateAddition of samplewith antigenand controls (titration)

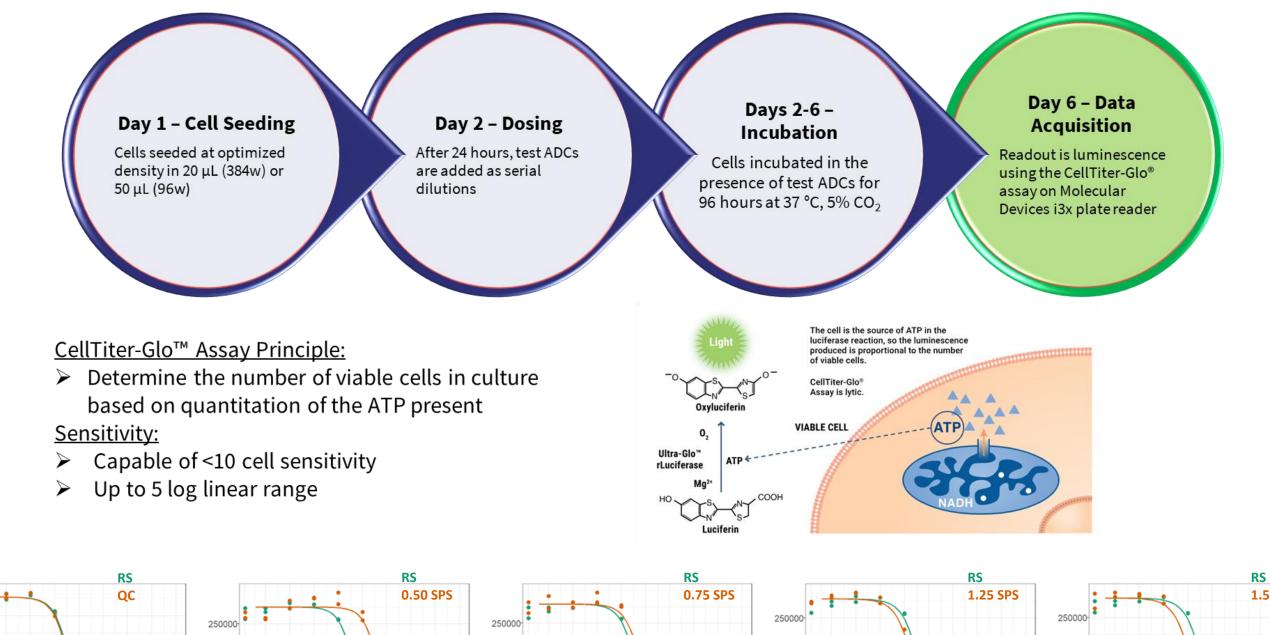

Addition of HRP-labeled secondary antibody

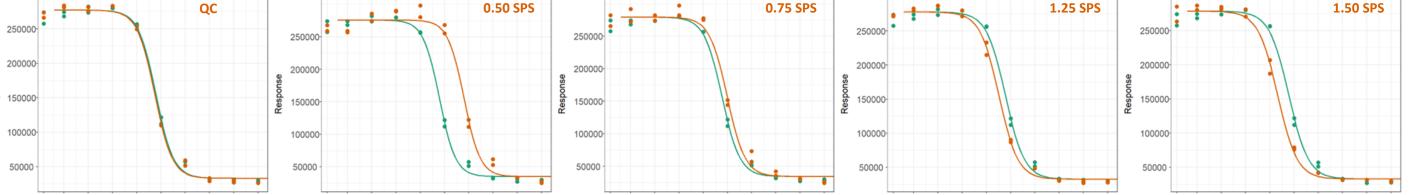

0.063755

Addition of TMB and detection

Early high throughput assay qualified to ensure CQAs are maintained during early development of the drug.

Mechanism of Action Reflective Cytotoxicity Assay

• In vivo assay

- Cell-based assay primary cells
- Cell-based assay cell line
 - Phenotypic assay
 - Reporter / activation assay
- Bindingassays
 - Cell-based
 - Biochemical
- Physiochemical assays

Abzena strikes a balance when developing an assay that is:

vance

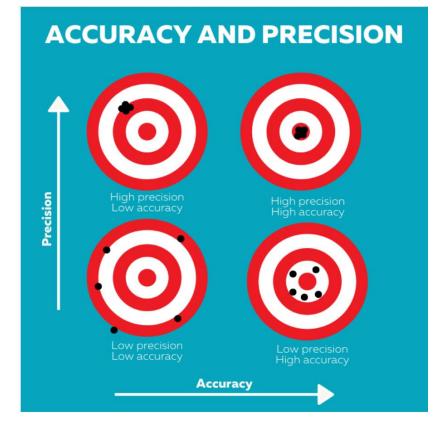

- Representative of the critical quality attributes (CQAs) required at the given stage of drug development.
- Accurate and precise to satisfy regulatory requirements

Suitability for Q

To reduce timelines and provide the critical support needed throughout drug development, Abzena develops bespoke assays to meet the exact needs of its clients.

As needs require, Abzena develops more complex assays to satisfy regulatory requirements to proceed to clinical trials.

Figure 3: Qualification data using simulated potency samples (SPS) for the MoA reflective bioassay developed at Abzena.

MoA reflective assay demonstrates killing of target cells in the presence of ADC.

Assay demonstrates potency within qualified ranges pre-defined for our projects.

Summary

At Abzena, our assay development process allows us to:

- Streamline design, development and manufacturing of ADCs all under one roof. Abzena provides phase-appropriate potency testing throughout.
- Efficiently develop assays using a data driven DoE approach with robust justifications for each decision taken.
- Provide qualified relative potency assays to support the drug development life cycle through to clinical trials.
